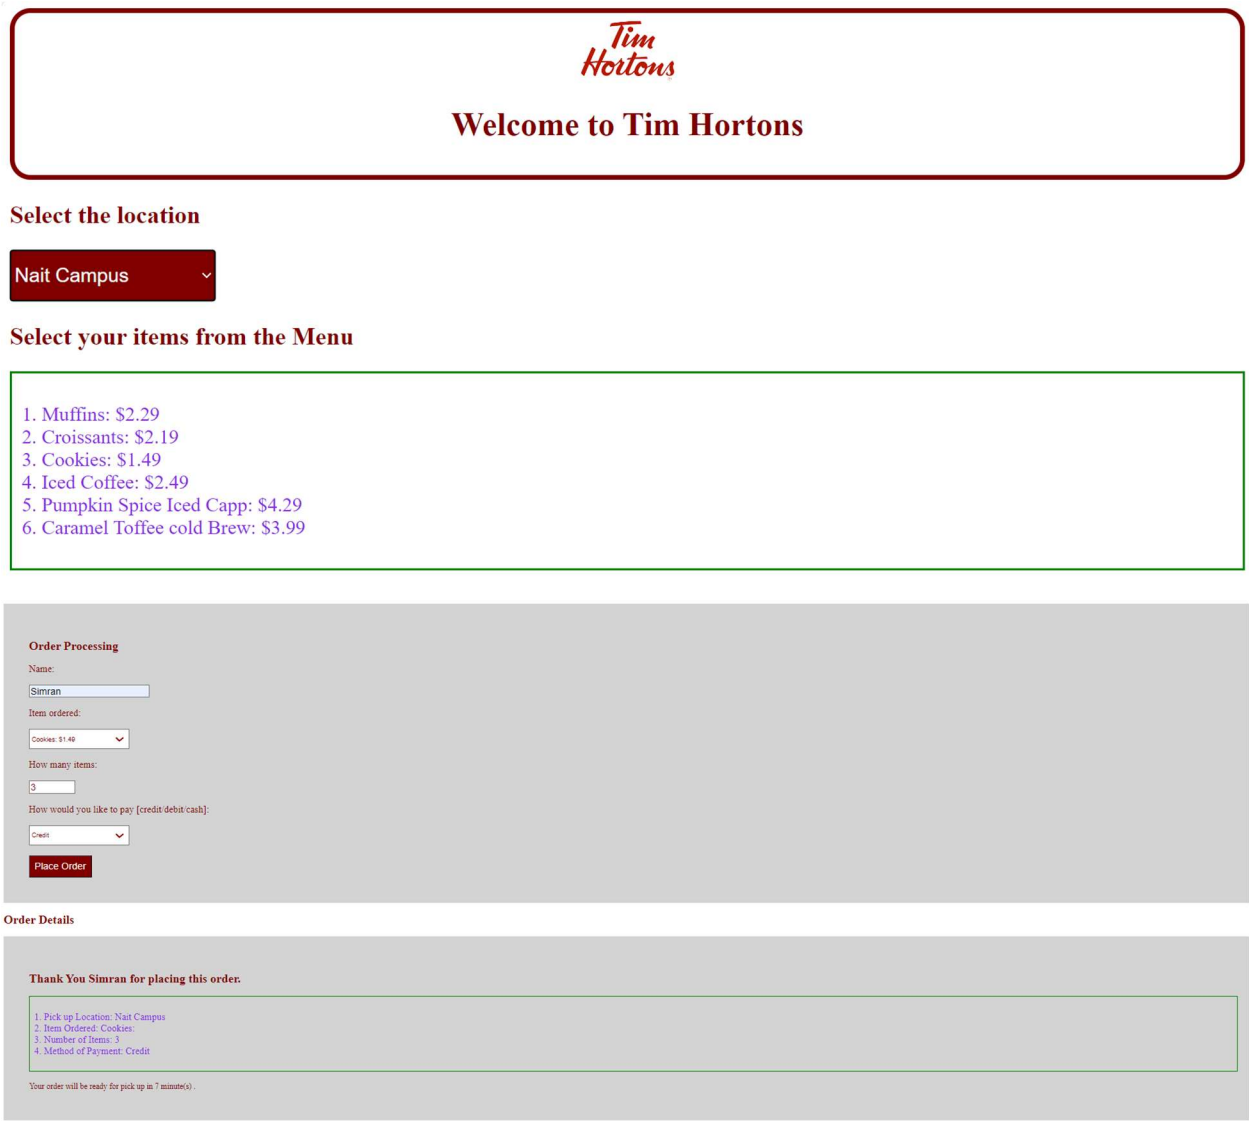
CMPE2550 – ICA06 [ASP]

Tim Hortons requires a basic page from where the user can obtain information regarding the different locations and menu items and should be able to place orders online from anywhere. Therefore, to help them you need to design a web solution for this. An example layout and very simple style has been shown below, but it is not mandatory to replicate exactly. Feel free to be artistic as you please, but it is advised to focus on the functionality first.



This ica will incorporate ASP Core functionality and brush up on some client-side skills such as AJAX calls and dynamic page updating. You may start by making Assignment 06 folder, then rename the elements appropriately.

Create a new ASP Assignment06 folder. You will require at least 4 files (exact names not required):

index.html This file will be your landing page.

script.js This page will process the actions from the index.html page.

style.css This page will be used to contain style information that may be required by the application logic.

Web Service This will be a service file(s)/ ASP.NET Core project containing data of the application.

Or you can create an ASP.NET Core project and then create client-side files under a folder. It is demonstrated in the demo as well.

PART 1: Welcome Message of the place

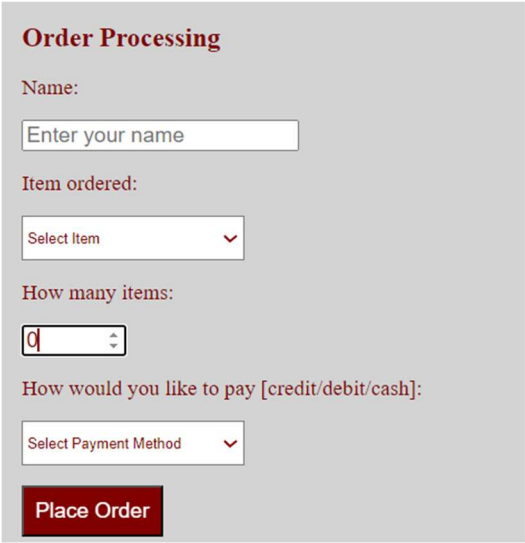
The very first thing which is required to make customers welcomed is a welcome message with a smile by the person attending the customer, and to greet customers online make an Ajax call on page load to bring out the greeting message with name of the restaurant which is "Welcome to Tim Hortons" from server application with "GET" method handler, and display it in the header of the page on client side.

PART 2: LOCATION SELECTION and MENU ITEMS

To place any order online before reaching at the pickup location, customer has to decide a pickup location [At the moment restaurant is not offering delivery option], so for that make another Ajax call to on page load to bring different locations of Tim Horton and Menu items offered at that location from the server side. Make sure to make use of "POST" method to make your call. Need to return array from the server side. Use any loop to construct an ordered list of the available menu items and a drop-down list of possible locations. Refer to picture above. Now the customer can decide the pickup location and item of food to be ordered.

PART 3: FORM PROCESSING

Finally, the customer has made up the mind about what is going to be ordered. Now the next task is to provide a basic form to the customer to make an order which can be processed by the restaurant before the customer is going to pick it up from the pickup location.

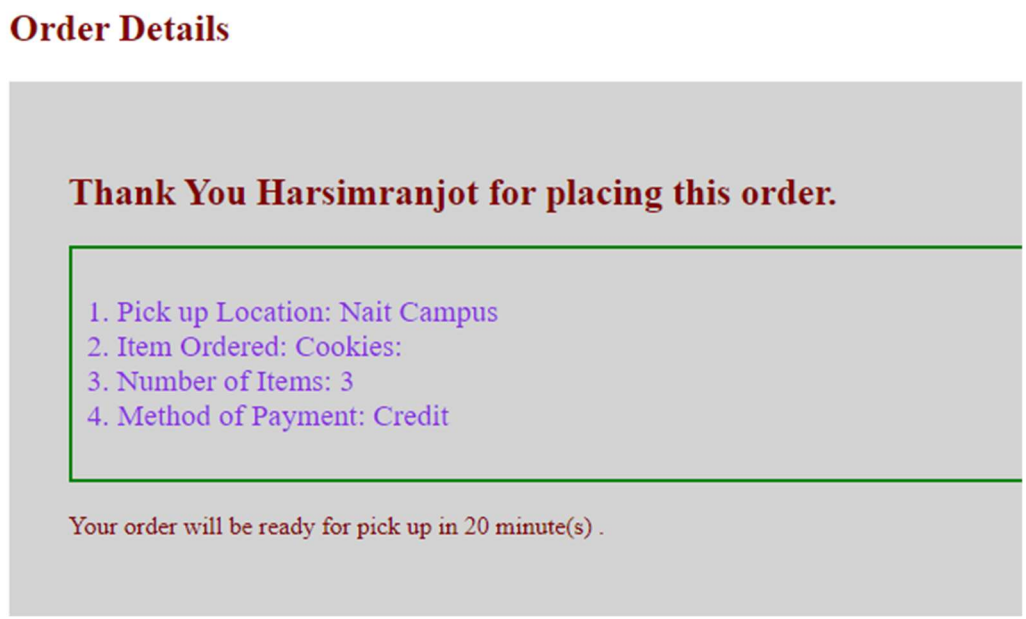


It should satisfy the following requirements:

- Name field should be a mandatory field.
- Items ordered and payment method options should be provided in the form of a drop-down list. Fill the item ordered with the data available from server application on page load.
- How many items field should be of number type so that user is not able to enter non-integer values.
- Place order button to place an order.

When the user presses the [Place order] Button, the submitted data will be cleaned and examined to ensure everything is provided. An appropriate error message should be displayed if either field is missing.

If everything is provided, submit the order to the restaurant [server side]. Once the order is processed by the restaurant [means received by the restaurant and estimated pick up time is decided] return the processed order details from the restaurant [server] and display it back to the customer under [Order Details] section for confirmation. Refer to the screenshot provided below. To calculate estimated time for order pickup, generate a random number between 5 and 30 on the server side because the restaurant is preparing your order from 5(less rush) to 30 minutes (peak hours). Possible sample is as follows.



Note: This will be a living document as it is the first time it is being delivered. If typos are encountered, or an explanation is not clear or seems incomplete, please approach your instructor about it so that the feedback may be passed to the document creator. If the fix is complex enough, this document will be added to or changed, and the class alerted. Do keep in mind that you are expected to do some of the thinking and specific design, so this document has not been designed as a step-by-step recipe for completing the assignment, but more intended as a discussion of the requirements.
